Contents

- **Why studying fast electron propagation**
- **X-ray spectroscopy study: preplasma effect;**
- **X-ray single-photon detection;**
- **Monochromatic X-ray imaging: a new technique;**
- **Latest experimental results;**
- **Perspectives & Conclusions**

Studying fast electron transport

Leo GIZZI, Omega Laser Facility Workshop, Rochester, NY, 29th April, 1st May 2009.

- The Fast ignition approach to Inertial Fusion Energy requires high current, fast electron beams to propagate efficiently in high solid density collisional plasmas;
- Transient magnetic fields and neutralising plasma return current occur;
- Return current will give rise to resistive thermal heating that will modify the spectral features of X-ray fluorescence;
- Knowledge is needed on the state of the material in which f.e. propagation occurs;
- X-ray spectroscopy is the principal tool for accomplishing this task;

The project

The HiPER project, now well into its preparatory phase, the EU as a European research infrastructures

Leo GIZZI, Omega Laser Facility Workshop, Rochester, NY, 29th April, 1st May 2009.

<http://www.hiper-laser.org/>

Scenario and motivation

basic ultraintense interactions and fast ignitor physics

- plasmas produced by laser intensities well above 10^{18} W/cm²
- expected current of several MA

Application in fusion research (fast ignitor)

J.S.Green et al., et al., (2005)

Need to investigate PROPAGATION AND ENERGY DEPOSITION of fast electron beam inside the material

Leo GIZZI, Omega Laser Facility Workshop, Rochester, NY, 29th April, 1st May 2009.

How to investigate f.e. transport

- Knowledge is needed on the applicability of X-ray techniques to f.e. transport studies in extreme conditions (diagnostic development);
- Foil targets can be used to investigate f.e. transport in solids and plasmas through detection of K- α emission;
- X-ray spectroscopy of shifted K- α components can be used to infer the electron temperature of the bulk target and to speculate on the role of refluxing of the fast electron beam at the target rear side;
- transport also plays a role in X-ray yield optimisation studies of laser driven X-ray sources;

Leo GIZZI, Omega Laser Facility Workshop, Rochester, NY, 29th April, 1st May 2009.

Our experimental method

- We use intense and ultraintense laser-foil interaction;
- Optical scattering is used to monitor interaction regime;
- Electron propagation is studied through X-ray fluorescence emission;
- Imaging of X-ray emission is resolved in energy;
- Multi-layer targets are used to follow f.e. propagation;
- Forward-escaping fast electrons are detected and measured (spectrum and angular distribution);

$K\alpha$ radiation mechanism

CALCULATED ION POPULATION VS. TEMPERATURE

calculated ion population vs. temperature in Ti

Fast electron energy deposition gives rise to local heating in the target substrate. Heating will generate weakly ionised (warm) dense matter.

E. Martinolli et al., PRE, 73(4):046402, Apr 2006.

CALCULATED SPECTRA FROM Ti

Leo GIZZI, Omega Laser Facility Workshop, Rochester, NY, 29th April, 1st May 2009.

Spectra calculated using the kinetic code flychk* for a cold/warm target and for a hot, critical density plasma. K-shell emission components fall in the 4.5 - 4.8 keV range

*H.-K. Chung et al., High Energy Density Physics, 1:3–12, 2005.

Space resolved measurements

- Energy resolved imaging is needed to identify regions of X-ray emission characterised by different physical conditions.
- Longitudinal propagation and energy deposition of fast electrons is usually studied by means of targets with a buried layer of a tracing element;
- Crystal imaging with toroidally bent crystals can be used to image out X-ray emission from the tracer layer at a given wavelength;
- Multi layer targets with multi-energy tracing element would provide a detailed f.e. propagation history;
- An extension of the standard pin-hole camera imaging has been used to achieve micrometer-resolution imaging with a few percent resolution in a wide spectral range above 1keV;
- The technique relies of the use of a low-noise CCD detector working in a low photon flux detection regime

Leo GIZZI, Omega Laser Facility Workshop, Rochester, NY, 29th April, 1st May 2009.

Direct X-ray Spectroscopy

Spectral analysis of X-rays generated by femtosecond laser-plasma interactions is performed by using a **low noise CCD array** to measure the charge produced by each photon

The X-ray flux incident of the CCD array is controlled to ensure that **the average number of photons per pixel is much less than one.**

- The image shows the result obtained with a Peltier cooled, 16 bits ccd array, after exposure to X-rays produced by a **single femtosecond laser-target interaction event.**

Algorithm

Leo GIZZI, Omega Laser Facility Workshop, Rochester, NY, 29th April, 1st May 2009.

Event identification

Subtraction of local background

Sum of charge over pixels of each event

Histogram of events for each class (one pixel, two pixels etc. ...)

180 μm

Extension to single shot measurement

- High energy laser experiments (e.g., RAL, OMEGA/EP, LULI) require single shot measurements;
- Our imaging technique requires >400 low flux images to collect a sufficient number of photons per spectral band to build up a full image;
- **Our approach is to use an array of closely spaced pin-holes and image out the source on a large area CCD array;**
- Custom array of pin-holes is needed due to the required diameter ($<10\mu\text{m}$), substrate thickness ($\gg 10\mu\text{m}$) and material. Also, geometry should be matched to achieve the required space resolution for a given source size and CCD specs.

First trial on custom pin-hole array (laser drilling at ILIL)

First single shot experiment

Single shot trial in progress at Prague PALS laser facility

General	Fundamental wavelength	1.315 μm
	Pulse duration	300 to 400 ps
	Pulse contrast (prepulses & ASE)	$\sim 10^{-7}$
	Repetition shot rate	25 min
	Output energy stability (over 10 shots)	$< \pm 1.5\%$
Main beam	Pulse energy at 400 ps	1 000 J
	Pulse power at 400 ps	3 TW
	Diameter	290 mm
	Conversion efficiency to 3 ω	55 %

Target: thick Ti foil
 Intensity: 10^{15} W/cm²
 Wavelength: 3 ω (438nm)
 Pulselength: 200ps
 Energy 60J
 Spot size.: 100 μm^2 , Target-PHA distance: 12cm PHA-CCD distance: 60cm;
 CCD array size: 1024x1024 pxls
 Pixel size: 13.5x13.5 μm^2 .

First single shot array X-ray image

Images have been obtained at a range of intensity levels down to the single photon detection regime.

Leo GIZZI, Omega Laser Facility Workshop, Rochester, NY, 29th April, 1st May 2009.

Identified photons (all energies)

CONCLUSIONS

- **EXTENSION OF THE SINGLE PHOTON DETECTION TECHNIQUE**
TO ENABLE μm -RESOLUTION, MONOCHROMATIC X-RAY IMAGING;
- **TECHNIQUE APPLIED TO DETECTION OF $K\alpha$ EMISSION**
TO INVESTIGATE FAST ELECTRON PROPAGATION IN MULTI-LAYER TARGETS;
- **INTERACTION OF RELATIVISTIC PULSES WITH MULTI-LAYER METALLIC TARGETS** show collimated propagation of fast electrons inside the material;
- ANALYSIS OF DIFFERENT SPECTRAL COMPONENTS SHOWS EVIDENCE OF BREMSSTRAHLUNG EMISSION from fast electron propagation;
- ENERGY-RESOLVED, μm -resolution X-ray imaging extended to the single-shot, experiments.

CONCLUSIONS

- **EXTENSION OF THE SINGLE PHOTON DETECTION TECHNIQUE**
TO ENABLE μm -RESOLUTION, MONOCHROMATIC X-RAY IMAGING;
- **TECHNIQUE APPLIED TO DETECTION OF $K\alpha$ EMISSION**
TO INVESTIGATE FAST ELECTRON PROPAGATION IN MULTI-LAYER TARGETS;
- **INTERACTION OF RELATIVISTIC PULSES WITH MULTI-LAYER METALLIC TARGETS** show collimated propagation of fast electrons inside the material;
- ANALYSIS OF DIFFERENT SPECTRAL COMPONENTS SHOWS EVIDENCE OF BREMSSTRAHLUNG EMISSION from fast electron propagation;
- MODELLING using a 3D hybrid code (PETRA) is in progress. Single layer calculations show significant consistency with experimental data. Multi-layer calculations are in progress.
- ENERGY-RESOLVED, μm -resolution X-ray imaging is being extended to the **single-shot**, high energy experimental regime.
