## Transport of Relativistic Electrons for Modeling Fast Ignition in the 2-D Hyrocode DRACO

J. A. Delettrez, S. Skupsky, C. Stoeckl, and P. B. Radha Laboratory for Laser Energetics University of Rochester 33rd Anomalous Absorption Conference Lake Placid, NY 22–27 June 2003 Summary

# We present integrated simulations of the interaction of the EP fast-ignitor beam with OMEGA cryogenic capsules

- The OMEGA EP laser will produce short-pulse (~20-ps), high-intensity beams (> 10<sup>19</sup> W/cm<sup>2</sup>) to study the physics of fast ignition.
- A relativistic electron transport model is being added to the multidimensional hydrocode *DRACO*.
- In this presentation, a simple penetration model is used to slow electrons from a monoenergetic constant beam source.
- Stagnation is modified by shocks driven by the electron-heated highdensity shell, depending on the timing of the beam:
  - an extra "spherical" kick at time of low shell  $\rho R$  (< 0.3 g/cm<sup>2</sup>)
  - one-sided displacement at peak shell  $\rho R$  (> 0.4 g/cm<sup>2</sup>)
- The order of magnitude increase in the neutron production rate is easily diagnosable.

## A direct-drive target was designed at OMEGA energy (25 kJ) to give > 300-g/cm<sup>3</sup> densities

CH – **5.8** μ**m** -DT **90** µm 10<sup>1</sup> Power (TW) 3 atm DT **1000** μm 10<sup>0</sup> 3 2 0 Δ Time (ns)

A 1-MeV electron has a range of about 0.4 g/cm<sup>2</sup>.

# Simulations were carried out with a 20-ps, 1-MeV electron beam with total energies of 400 J and 1 kJ

- Electrons are instantaneously transported through the target.
- They give their energy to the background electrons using a penetration depth formulation applied in each zone.

## For low density (250 g/cm<sup>3</sup>) the beam heats the two sides of the target and creates colliding shocks at the center

### For high density (500 g/cm<sup>3</sup>) the beam heats only one side of the target sending a shock through the center

#### The fast-ignitor beam creates a burst of neutrons that can be easily diagnosed LLE $\rho = 500 \text{ g/cm}^3$ 400-J pulse **10-μm radius 10-µm radius** 250 g/cm<sup>3</sup> 1 kJ 10<sup>26</sup> $Y = 2.4 \times 10^{15}$ $Y = 4.6 \times 10^{15}$ Production rate (1/s) 400 J $Y = 1.2 \times 10^{15}$ 10<sup>25</sup> 500 g/cm<sup>3</sup> No fast No fast electrons $Y = 1.2 \times 10^{152}$ electrons $Y = 4 \times 10^{14}$ 10<sup>24</sup> 3.925 3.975 4.000 3.90 3.92 3.94 3.96 3.98 4.00 3.900 3.950 Time (ns) Time (ns)

## Future work includes improvements in the electron beam source and the transport

- Add a spectrum at a temperature given as a function of the fast-ignitor laser beam.
- Use a slowing-down formula for the electron energy loss instead of a penetration depth model.
- Include beam spread.
- Add more realistic physics (return current, electric fields, magnetic fields) to the transport, either explicitly or semiempirically based on the results of 3-D PIC code simulations.
- Simulation of implosions with expected illumination and inner ice nonuniformites.

Summary/Conclusions

## Irradiation by the EP fast-ignitor beam of OMEGA-imploded cryogenic capsules provides sensitive observables

- The OMEGA EP laser will produce short-pulse (~20-ps), high-intensity beams (>10<sup>19</sup> W/cm<sup>2</sup>) to study the physics of fast ignition.
- A relativistic electron model is being added to the multidimensional hydrocode *DRACO*.
- In its first iteration, a simple penetration model is used to slow electrons from a monoenergetic beam source.
- The fast-ignitor beam lead to an increase in the neutron production rate of about an order of magnitude.
- A secondary implosion driven by the heated high-density shell can be either "spherical" or one-sided depending on the electron source beam energy.
- Many improvements in the model are planned to make it more realistic.
