Time-Resolved Measurements of Compressed Shell Temperature and Areal Density with Titanium-Doped Targets on OMEGA

Laboratory for Laser Energetics, U. of Rochester

Time-resolved spectroscopic measurements of self-backlit implosions on the 60-beam, 30-kJ UV OMEGA laser system are used to determine shell temperature and areal density at peak of compression. The target shells have titanium-doped layers to probe temperature and areal density inside the shell. Both time-resolved and time-integrated measurements have been taken with 1-mm-diam, 20-µm-thick shells filled with 3 or 15 atm of D₂. The shell conditions are studied with 1-ns square, 6:1-contrast, 2.4-ns pulse shapes. The temperature of the hot part of the shell and the core has been measured from the continuum emission of the target, the temperature of the warm part of the shell has been measured from the spectral position of 1s-2p titanium absorption, and the minimum shell temperature has been measured from the spectral shift of the titanium K edge. The shell areal density has been measured from the titanium 1s-2p and K-edge absorption. This work was supported by the U.S. Department of Energy Office of Inertial Confinement Fusion under Cooperative Agreement No. DE-FC03-92SF19460.

Summary

Measured peak areal density of the shell is \( \sim 100 \text{ mg/cm}^2 \) with 20-\( \mu \text{m} \)-thick shells filled with 3 atm of \( \text{D}_2 \).

- Shell temperature and areal density are diagnosed using titanium-doped layers.

- Conditions in a “cold” shell (\( T < 500 \text{ eV} \)) are measured with \( k \)-edge absorption, in a “warm” shell (\( T \sim 600–700 \text{ eV} \)) with 1\( s \)–\( 2p \) absorption, and in a “hot” shell (\( T \sim 1.0–1.5 \text{ keV} \)) with continuum emission.

- Measured shell areal density at peak compression is at least 100 mg/cm\(^2\).

- Shell temperature varies from 200 eV to 1.5 keV at peak compression.
Targets with inner and offset titanium-doped layers are used to probe conditions in the shell.
Measured spectra contain information about shell areal-density and temperature evolution.

1. “Cold” shell ($T < 500$ eV) areal density from $K$-edge absorption
2. “Warm” shell ($T \sim 600–700$ eV) areal density from 1s-2p absorption
3. “Hot” shell ($T \sim 1.0–1.5$ keV) temperature from continuum emission
Electron temperature from continuum emission is derived from the fit to experimental data.

\[ \text{fit} = \left( \exp \frac{E}{T} - \mu(E) \right) \]  
\[ T = \text{temperature} \]  
\[ (pr) = \text{cold areal density} \]
“Warm” shell areal density and temperatures is derived from the region of 1s-2p absorption

\[ \text{fit} = \left( \exp \frac{E}{T} - \mu(E) \right) [\rho r] \]

\[ T = \text{temperature} \]

\[ (\rho r) = \text{cold areal density} \]
“Cold” shell ($T < 500$ eV) areal density is derived from the $K$-edge absorption

$$\text{fit} = \exp\left(\frac{E}{T} - \mu(E) [pr]\right)$$

$T =$ temperature
$(pr) =$ cold areal density

Inner layer
- CH
- D$_2$
- 3 atm
- 20 $\mu$m

Offset layer
- CH
- D$_2$
- 3 atm
- 20 $\mu$m

**Graphs:**
- Spectral intensity vs. Time (ns)
- Cold areal density vs. Time (ns)
SSD improves target performance with pulse shape PS26
In implosions with PS26 the shell is colder and achieves less areal density than with the 1-ns square pulse shape.
Shell areal density is higher in implosions with 1-ns square pulse shape than with PS26

Assumption: Half of the shell is ablated in the acceleration phase, and the rest is compressed as a titanium-doped layer.
Summary/Conclusion

Measured peak areal density of the shell is \( \sim 100 \text{ mg/cm}^2 \) with 20-\( \mu \text{m} \)-thick shells filled with 3 atm of \( \text{D}_2 \).

- Shell temperature and areal density are diagnosed using titanium-doped layers.

- Conditions in a “cold” shell \((T < 500 \text{ eV})\) are measured with \(k\)-edge absorption, in a “warm” shell \((T \sim 600–700 \text{ eV})\) with 1s–2p absorption, and in a “hot” shell \((T \sim 1.0–1.5 \text{ keV})\) with continuum emission.

- Measured shell areal density at peak compression is at least 100 mg/cm\(^2\).

- Shell temperature varies from 200 eV to 1.5 keV at peak compression.
