# Outline

---

- Charged particle measurements on OMEGA
- Shock and compression components of D-<sup>3</sup>He proton spectrum
- Effect of capsule parameters on timing and yield
- Temperature inferred from shock measurements
- Sources of shock spectral line broadening

# Measurements of charged particles provide spectral\*, spatial and temporal information

## “Wedge-Range-Filter” spectrometers (WRFs)

Particle energies identified from local thickness  $t$  and diameter of etched proton tracks in CR-39.

## Magnet-based spectrometers (CPSs)

Particle energies identified from trajectories.

\*F.H. Seguin et al, Rev. Sci. Instr. (to be published)

# Measurements of charged particles provide spectral, spatial and temporal information

## “Wedge-Range-Filter” spectrometers (WRFs)

*Spectra of  $D^3He$  p at multiple angles*

## Magnet-based spectrometers (CPSs)

*Spectra of  $D^3He$  p,  $\alpha$  and DD p, T,  $^3He$*

## Proton temporal diagnostic (PTD)

*Time history of  $D^3He$  burn rate*

## Proton Core Imaging Spectrometer (PCIS)

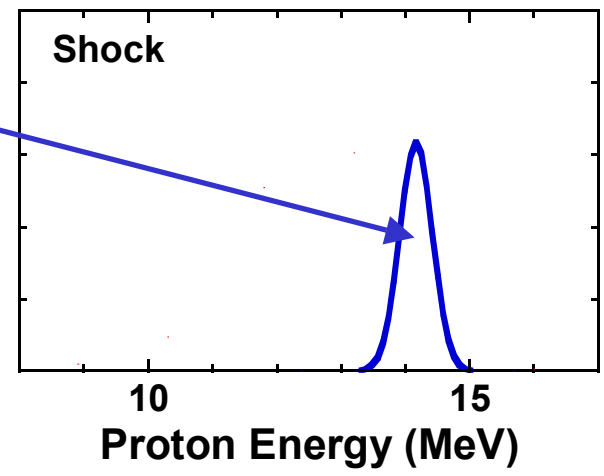

*Radial profiles of burn for DD at shock and  $D^3He$  at compression*

# Spectra of D<sup>3</sup>He protons are routinely measured on OMEGA

# D<sup>3</sup>He proton spectra can be divided into shock\* and compression components

From compression component: • Yield  
•  $\Delta\langle E \rangle \sim \rho R$

From shock line: • Yield  
•  $\Delta\langle E \rangle \sim \rho R$   
• line width

\*R.D. Petrasso et al, Phys. Rev. Lett. (to be published)

# Shock and compression components occur at different times

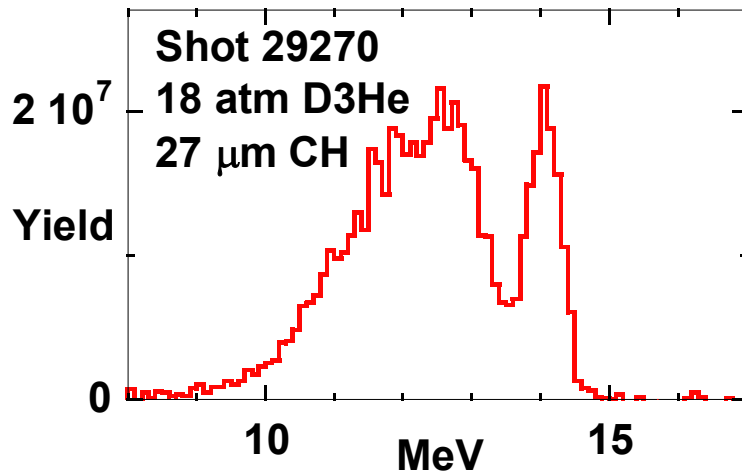

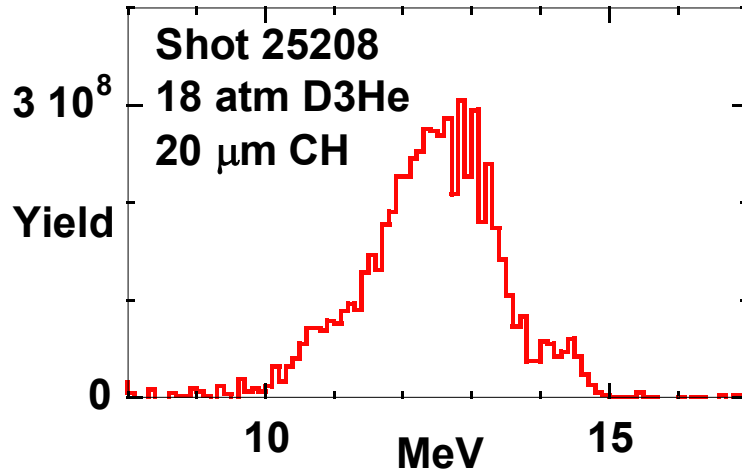

# 1D simulations predict a smaller interval between shock and bang time for thinner shells

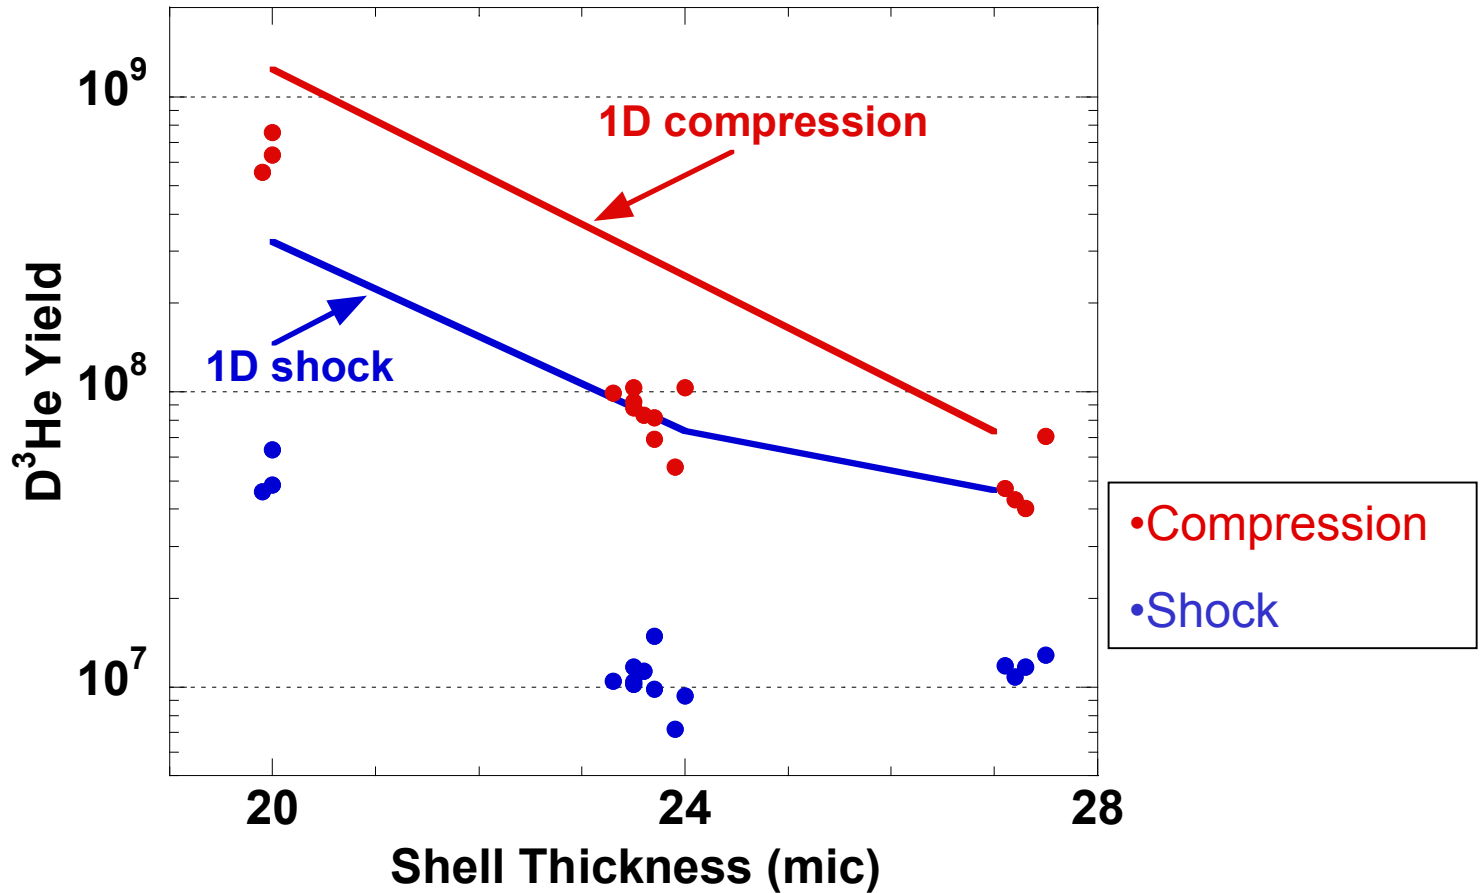

1D Simulated D<sup>3</sup>He Proton Rate

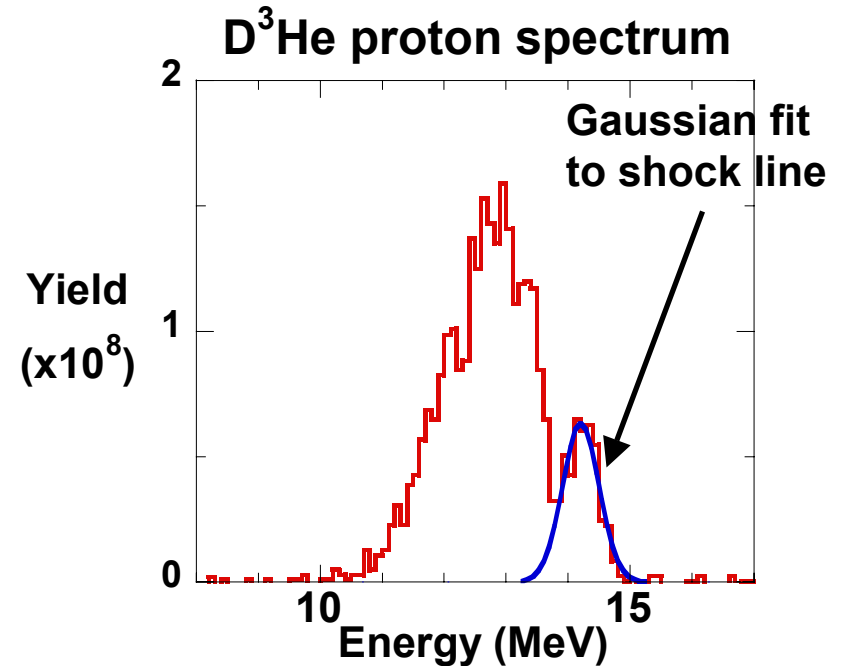

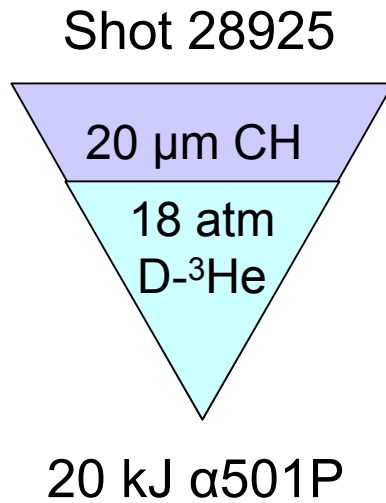

# Shock and compression components are strongly dependent on capsule parameters

# Shock and compression yields compared to 1D simulations

# Ion temperature can be estimated assuming line width comes from doppler broadening

$$\sigma_{\text{shock}}^2 = \sigma_{\text{doppler}}^2 + \sigma_{\text{instrument}}^2 + \sigma_{\text{other}}^2$$

If  $\sigma_{\text{other}}^2$  is neglected, derived shock temperature is:

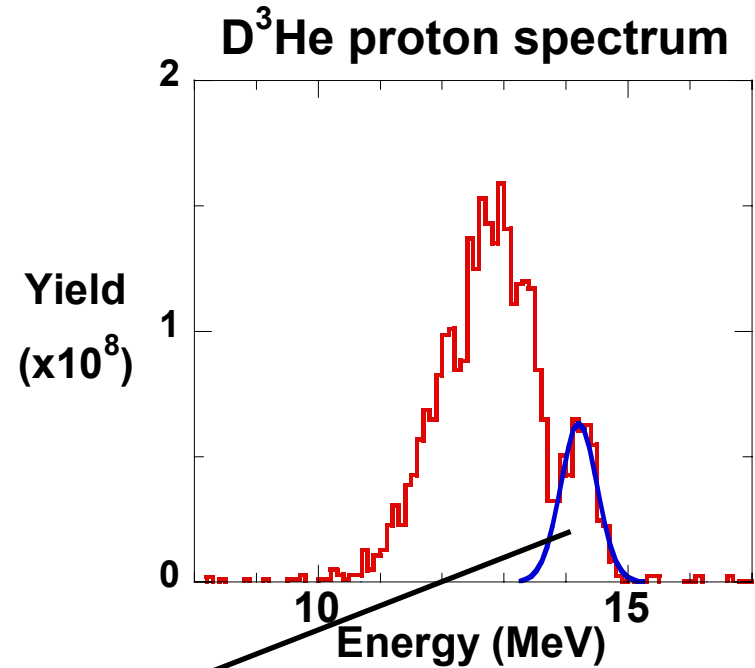

$$\langle T_i \rangle_{\text{width}} \approx 9.8 \text{ keV}$$

# Ion temperature can be estimated using yields of different nuclear reactions

$$Y_{DD} \approx 1.6e8$$

$$Y_{D^3He} \approx 4.9e7$$

# Ion temperature can be estimated using yields of different nuclear reactions

DD proton shock spectrum

D<sup>3</sup>He proton spectrum

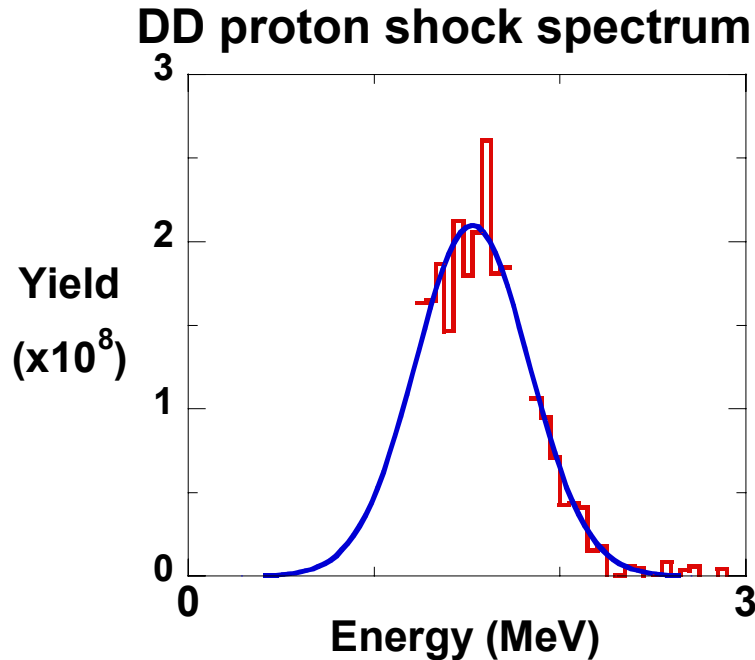

$$\left. \begin{aligned} Y_{DD} &\approx 1.6e8 \\ Y_{D3He} &\approx 4.9e7 \end{aligned} \right\}$$

Yield Ratio vs Temp

$\langle T_i \rangle$  ratio  $\approx 6.6$  keV

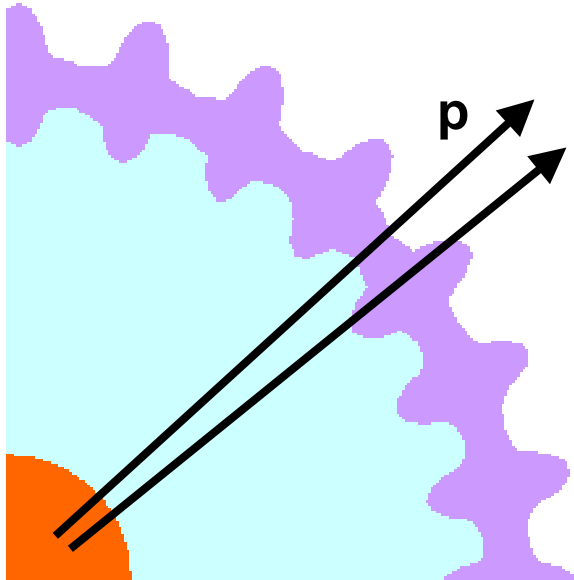

# Comparison of temperatures derived from different methods

Discrepancy hints at other sources of broadening

$$\left\{ \begin{array}{l} \langle T_i \rangle_{\text{ratio}} \approx 6.6 \text{ keV} \\ \langle T_i \rangle_{\text{width}} \approx 9.8 \text{ keV} \end{array} \right.$$

# Broadening due to high mode $\rho R$ modulations during the shock flash

Broadening from  
high mode  $\rho R$  variations  
at shock time

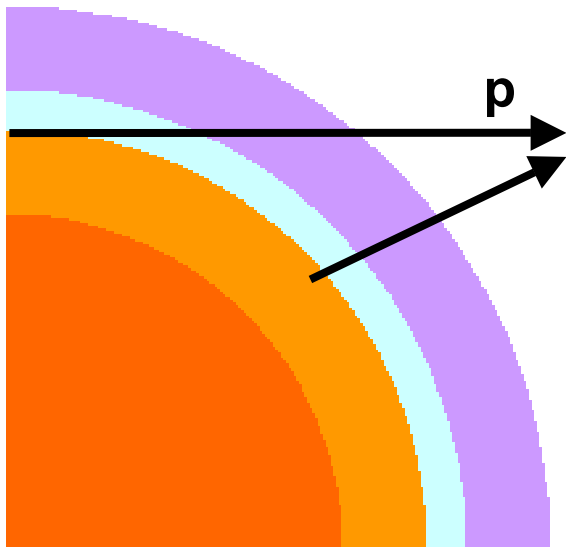

Temp difference constrains  
high mode amplitude < 40%

$$\begin{aligned} \langle T_i \rangle_{\text{ratio}} &\approx 6.6 \text{ keV} \\ \langle T_i \rangle_{\text{width}} &\approx 9.8 \text{ keV} \end{aligned}$$

# Broadening due to geometrical effects from a spatially extended source

---

**Broadening from geometry effects due to spatial extent of source region**

**PCIS can directly measure the extent of the source region**

**For more on PCIS:**

R. D. Petrasso <i>et al.</i>	GO2.015
B. E. Schwartz <i>et al.</i>	KP1.147

# Temporal broadening due to $\rho R$ evolution over finite interval of the shock flash

1D simulated proton rate and  $\rho R$

Broadening from  
 $\rho R$  evolution during  
shock flash interval

Development of PTD will enable  
measurement of shock width

1D simulation anticipates that:

Over  $\sim 150$  ps shock interval,  
 $\rho R$  evolves from  $\sim 10$  to  $\sim 17$   $\text{mg}/\text{cm}^2$

# Summary

---

- $\rho R$  and yield at shock coalescence and bang time are studied using DD proton and D- $^3\text{He}$  proton spectra.
- Shock and compression yields are reduced for targets with thicker shells.
- Charged particles can be used to study capsule conditions during shock coalescence, including
  - Ion temperature
  - High mode ( $\ell \sim 50$ )  $\rho R$  modulations
  - Spatial extent
  - Temporal evolution

# Future work

---

- Develop Proton Temporal Diagnostic (PTD) and use to directly measure the timing and width of shock flash and compression burn
- Quantify sources of shock spectral line broadening in order to investigate possible high mode ( $\ell \sim 50$ )  $\rho R$  variations at shock time
- Investigate possible low mode ( $\ell \sim 2$ )  $\rho R$  structure growth between shock and bang time
