62nd Annual Meeting of the American Physical Society Division of Plasma Physics
Tuesday, November 9, 2021
Measurements of the neutron energy spectrum emitted from high temperature shock driven implosions are inconsistent with a Maxwellian plasma model

- The primary DT and DD neutron energy spectrum generated in laser direct drive inertial confinement fusion implosions were measured using a suite of neutron time of flight (nTOF) detectors on the OMEGA 60 laser

- Measurements of the primary DD neutron energy spectrum are inconsistent with a Maxwellian plasma model for the high-temperature, more-kinetic-like experiments

- Vlasov–Fokker–Planck (VFP) simulations reproduce the trend observed in the primary DD neutron energy spectrum measurements and suggest the presence of a bimodal ion velocity distribution in the high-temperature experiments

These results indicate that inferring a thermal plasma ion temperature from primary neutron energy spectrum measurements is not possible for kinetic plasmas

1. B. Appelbe, et al., GO07.00008, this conference
The neutron energy spectrum emitted from a single temperature Maxwellian plasma is well understood.

The neutron energy spectrum emitted from a single temperature Maxwellian plasma is well understood.

\[ \Delta E_{th} = \beta \langle V^2 \rangle + \gamma \langle K \rangle \]

The neutron energy spectrum emitted from a single temperature Maxwellian plasma is well understood.

\[ \Delta E_{th} = \beta \langle V^2 \rangle + \gamma \langle K \rangle \]

For a single temperature Maxwellian plasma a unique relationship exists between the Gamow energy shift and the plasma temperature.

A Maxwellian plasma with a distribution of ion temperatures in space and time can reduce the Gamow shift for a given spectral temperature.

Measurements that fall outside of the Maxwellian fluid regime would provide direct evidence of a non-Maxwellian distribution.

2. A. Crilly, et al., in preparation
A set of experiments were performed to test the Maxwellian plasma neutron energy spectrum model.

\[ T_i < 6 \text{ keV} \quad N_k < 1 \]

\[ T_i \sim 10 \text{ keV} \quad N_k \sim 1 \]

\[ T_i > 15 \text{ keV} \quad N_k > 1 \]

The laser power, shell thickness, and gas pressure were varied to achieve different conditions.

\[ N_k = \frac{\lambda_{ii}}{L} \propto \frac{T_i^2}{\rho R} \]
The 3dnToF detector suite was used to measure the primary DT and DD neutron energy spectrum along multiple lines of sight.

The plasma apparent ion temperature, bulk velocity, and Gamow shift was inferred from these measurements.

Example 3dnToF data (P7 DD neutrons)

Peak shift due to Gamow velocity shift

Measurements of the Gamow shift agree with the Maxwellian fluid theory for low temperature implosions but show discrepancies for high temperature implosions.

The anomalous DD data points suggest the presence of a non-Maxwellian ion velocity distribution in these kinetic implosions.
The multi-ion Vlasov-Fokker-Planck (VFP) code iFP\textsuperscript{1} was used to study the anomalous high temperature implosion results

- iFP calculations were initiated half way through the laser pulse using the hydrodynamic profiles from a radiation hydrodynamic simulation
- The ion velocity distribution of each ion species was calculated by solving the VFP equations on a discrete velocity grid

The long mean free paths leads to a smoothing out of the implosions shock front

\textsuperscript{1} W. T. Taitano, Physics of Plasmas 25 (5) (2018).
The diffuse shock front leads to a bimodal ion velocity distribution at peak neutron production in the iFP simulations.

The bimodal ion velocity distribution produces a narrower neutron energy spectrum.

1. B. Appelbe, et al., GO07.00008, this conference
The iFP simulations reproduce the trend observed in the high temperature DD primary neutron spectra data.

The iFP bimodal ion velocity distribution predictions are consistent with the high temperature DD measurements.
